

Abstract:

A pistol comprising a grip (1), a barrel slide (2) movable on the former in firing direction, and a barrel (3) capable of being interlocked with the barrel slide is to be simple to lock and get a convenient, straight-line recoil behavior. This is achieved in that the first locking means is a projection (29) provided on the outer contour of the barrel (3) and having a forward-facing first inclined surface (40), the second locking means is a lever (20) pivotably guided in the barrel slide (2) and including a dog (24) having a rearward-facing, second inclined surface (42) cooperating with the first inclined surface, and the unlocking means is a stop (33) provided in the grip and cooperating with a lug (32) of the barrel (3). There, the angle of inclination (41) of the inclined surfaces is chosen such that when the barrel (3) impacts against the stop (33) and the barrel slide (2) continues its movement, the inclined surfaces (40, 42) are capable of sliding off each other, and the lever (20) is pivoted against the force of a spring (25) such that the dog (24) releases the barrel slide (2).
